Abstract. Introduction: In the 1960s, it was discovered that there was a significant need for more physicians to serve the U.S. population, especially in rural and medically underserved communities. The Physician Assistant profession was built with the hope of being an extension to physicians to help meet these needs. However, there continues to be large numbers of communities in every state that lack access to health care. The purpose of this study was to explore the factors influencing Physician Assistant practice location choice.

Methodology: A retrospective cross-sectional study of PA student records in a mid-western rural-focused physician assistant program was conducted. Application data from PA graduates in 2003, 2004, and 2005 were evaluated for desired community size of practice location at the time of application compared to actual job placement and community size after graduation. A written survey was mailed to the same classes of graduates to assess factors that influenced selection of their first and current practice location. Data were analyzed using frequency counts and chi-square tests.

Results: There was a 44% response rate from the 126 eligible to participate in the survey. It was noted that 60% of applicants listed their preference for family practice, however, less than one-third of graduates were currently working in the family practice specialty. Similarly, applicants noted a preference to work in rural areas, but upon graduation for their first job and current job they tended to work in urban areas by a large percentage. There were five different factors with significant relationships in regard to PA practice location: Significant others support of location, quality of life, employment opportunities for the significant other, scope of practice and recreation. A significant others support of location appeared to be most important.

Conclusions: Choice of employment at the time of application compared to graduation was markedly different. Choice of practice location did not appear to be a decision made by the graduate physician assistant alone, but also in conjunction with their significant other.

1. Introduction

In the 1960’s, it was discovered that there was a significant need for more physicians to serve the U.S. population, especially in rural and medically underserved communities. The Physician Assistant profession was built with the hope of being an extension to physicians to help meet these needs.
3. Conclusions

The question should be raised: “Are we really getting to the root issue of what calls graduate physician assistants to urban areas over rural areas with such magnitude?” This study has attempted to address some of the elements underlying this ongoing problem. It has been found that “graduates who study in an educational setting with a mission-driven commitment to rural health, care for these populations in their professional practice.”[1] However, it appeared in this research that choice of practice location was not a decision made by the graduate physician assistant alone, but also in conjunction with their significant other, which seemed to be more influential than any other factor alone. Further research will be required to determine whether the findings of this study can be generalized to the physician assistant profession as a whole.

4. Acknowledgements

The researchers wish to express their gratitude to the PA Class of 2008 for their assistance in providing feedback regarding the survey. The PA faculty also contributed influential suggestions in the same manner. The secretarial staff in the office of Physician Assistant was responsible for providing blinded demographic information for the classes involved in the study as well as coding and recoding identifying information from the participants to ensure confidentiality. This project was funded in part by the Workforce Diversity Initiative Grant, US/DHHS, grant number D57HP05123, 2005-2008, Richard Muma, PI.
