LacI-DNA-IPTG Loops:
Equilibria among Conformations by Single-Molecule FRET

Abstract: The E. coli Lac repressor (LacI) tetramer binds simultaneously to a promoter-proximal DNA binding site (operator) and an auxiliary operator, resulting in a DNA loop, which increases repression efficiency. Induction of the lac operon by allolactose reduces the affinity of LacI for DNA, but induction does not completely prevent looping in vivo. Single molecule fluorescence resonance energy transfer (SM-FRET) on a dual fluorophore-labeled LacI-9C14 loop showed that it adopts a single, stable, high-FRET V-shaped LacI conformation. Ligand-induced changes in loop geometry can affect loop stability. SM-FRET confirms that the high-FRET LacI-9C14 loop is only partially destabilized by saturating IPTG. FRET histograms suggest that the remaining population is a mixture of lower-FRET states ascribed to specific nonspecific or extended LacI loops, not free DNA.

1. Introduction

The control of the lac operon in E. coli by Lac repressor (LacI) is a classic example of negative gene regulation. The LacI homotetramer (a dimer of dimers) has the ability to bind two operator sites simultaneously, forming a DNA loop. In part, the biological function of looping is that binding of one dimer to its operator increases the effective local concentration of the other operator around the other dimer, leading to increased occupancy of the second operator.

Probing the role of inducers, anti-inducers, and other allosteric effectors is important in understanding the regulation of protein-DNA looped complexes. In the presence of the artificial inducer, isopropyl-β-D-thiogalactoside (IPTG), there is about a 1000-fold decrease in the affinity of LacI for the operator. One IPTG molecule binds to the core domain of one monomer of LacI. The reorientation of the core domain increases the distance between DNA binding headpieces in a dimer, destabilizing the strong interactions between the headpiece and the DNA operator (figure 1).

Our interest is in mutual interactions among inducer binding, DNA site selection, and DNA loop stability, and therefore we focus here on conditions where inducer is saturating, the DNA is designed to form exceptionally stable loops, and the protein:DNA ratio is ~1. A complete quantitative understanding of the lac operon, and by extension all genes regulated by ligand-responsive DNA looping proteins, will require confronting a more complete structural and thermodynamic characterization of all of the possible protein-DNA-effector complexes.

SM-FRET on freely diffusing LacI-DNA loops allows us to analyze population distributions directly as opposed to the average properties measured in a bulk experiment, and the efficiency of energy transfer should be highly sensitive to changes in loop geometry.

2. Experiment, Results, Discussion, and Significance

Fluorescently labeled 9C14: Fluorescently labeled oligonucleotides 56 nucleotides in length were used as PCR primers for synthesis of the 9C14 DNA with Alexa Fluor® 555 (donor) and Alexa Fluor® 647 (acceptor) fluorophores. Fluorophores were conjugated to oligonucleotides synthesized with an amino dT C-6 internal modification (T* below: iAMMC6T). Fluorescently labeled oligonucleotides were purified on a 12%
polyacrylamide (40:1 (w/w) acrylamide: bis-acrylamide), 8 M urea gel. The primers were excised, eluted, phenol-
chloroform extracted and ethanol precipitated. Dual fluorophore labeled DNA constructs were synthesized using the
Phusion™ High-Fidelity PCR System with the template described above. PCR reactions (50 μL) contained 40
picograms of template, 200 μM of each dNTP, 1 μM each labeled primer, 1X Phusion HF Reaction Buffer, and 2
units of Phusion™ High-Fidelity DNA Polymerase. PCR cycling conditions were the following: 94.0°C for 1 min,
55.0°C for 30 s, 60.0°C for 30 s, 72°C for 1 min, for 35 cycles. Purification was carried out as described for the
radiolabeled DNA.

SM-FRET measurements: Single-molecule FRET was done essentially as described. Initial LacI titration experiments were used to determine the optimum
concentration of LacI to be used. SM-FRET IPTG measurements were conducted at
1 nM 9C14 and 1-1.5 nM LacI in LacI buffer. IPTG was added at various
concentrations and stages as described in the text. Samples were allowed to
equilibrare at room temperature (20°C) for at least 5 min. Single molecule studies
were performed with an oil immersion objective inverted microscope (Fluar, 100X,
N.A. =1.3, Carl Zeiss, Oberkochen, Germany) with standard methods. Excitation at
514 nm was from an argon ion laser focused 10 μm into the sample from the glass-
liquid interface. The objective collects the fluorescent burst data as the molecules
travel through the beam, and it is then directed through a notch filter (Kaiser Optical,
Ann Arbor, MI) to remove the excitation wavelength of the laser. The emitted light is
subsequently split between two avalanche photodiode single photon counting
modules (SPCM-AQR-15, PerkinElmer Optoelectronics, Vaudreuil, Quebec) using a
dichroic beam splitter (625DCLP, Chroma, Rockingham, VT). The photon counts are
recorded on separate channels of a counter/timer board (PCI 6602, National
Instruments, Austin, TX) in 1 ms time bins. The SPCMs are connected to the
counter/timer board directed by Labview 6.0 (National Instruments) software.

Results: We compare the FRET results on loop stability with an
electrophoretic mobility shift assay (EMSA). Use SM-FRET experiments to
investigate conformational changes caused by the addition of IPTG to pre-looped
LacI-induced DNA complexes (figure 2).

3. Conclusions
SM-FRET, a convenient method to study DNA looping and binding. Effector
molecules and architectural DNA binding proteins regulate loop shape and stability.
Inducer bound Lac repressor undergoes a conformational change that allosterically
affects the headpiece and core domains of the structure resulting in dramatically
decreased affinity for DNA. The high local concentration of the operators allows the
formation of LacI-DNA loops despite saturating [IPTG] in the supercoiled DNA
environment.
